MAXIM

Calibrated 12-Bit ADC with T/H and Reference

MAX178

General Description

The MAX178 is a complete, calibrated 12-bit A/D converter (ADC) which includes a precision voltage reference, track-and-hold, and conversion clock. Internal calibration circuitry maintains true 12-bit performance over the full operating temperature range without external adjustments. In addition, each conversion includes an auto-zero cycle which reduces zero errors to typically below 100µV.

CHIP SELECT, READ, and WRITE inputs are included for easy microprocessor interfacing without additional logic. 2-byte, 12-bit conversion data is provided over an 8-bit three-state output bus. Either byte may be read first. Two converter busy flags facilitate polling of the converter's status.

The MAX178's analog input range is 0V to +5V when using a +5V reference. The MAX178A's internal reference accuracy is ±0.3%, while the MAX178B is intended for use with an external reference.

Applications

Digital-Signal Processing

Audio and Telecom Processing

High-Speed Data Acquisition

High-Accuracy Process Control

Features

- ♦ **Continuous Transparent Calibration of Offset and Gain**
- ♦ **True 12-Bit Performance without Adjustments**
- ♦ **T/H Front End and Internal Reference**
- ♦ **DC and Dynamically Specified**
- ♦ **Zero Error Typically <100µV**
- ♦ **Standard Microprocessor Interface**
- ♦ **24-Pin DIP and Wide SO Packages**

Ordering Information

Pin Description

PIN	NAME	FUNCTION
1	CAZ	Auto-Zero Capacitor Input. Connect other end of capacitor to AGND.
2	AIN	Analog Input
3	N.C.	No Connect
4	REFIN	Voltage Reference Input. The MAX178 is specified with REFIN = +5V.
5	AGND	Analog Ground
6	DGND	Digital Ground
7	V_{CC}	Logic Supply. Digital inputs and outputs are TTL compatible for V_{CC} = +5V.
8-15	DB0-DB7	Three-State Data Outputs. Active when $\overline{CS}$ and $\overline{RD}$ are brought low. Individual pin functions depend upon BYTE SELECT (BYSL) input.

DATA BUS OUTPUT, $\overline{CS}$, $\overline{RD}$ = LOW		
PIN	BYSL = HIGH	BYSL = LOW
8	BUSY (Note 10)	DB7
9	LOW (Note 11)	DB6
10	LOW (Note 11)	DB5
11	LOW (Note 11)	DB4
12	DB11 (MSB)	DB3
13	DB10	DB2
14	DB9	DB1
15	DB8	DB0 (LSB)

PIN	NAME	FUNCTION
16	$\overline{RD}$	READ Input. Used with CS to enable the three-state data outputs. RD is active low.
17	$\overline{CS}$	CHIP SELECT Input. Used with either $\overline{RD}$ or $\overline{WR}$ for control. $\overline{CS}$ is active low.
18	$\overline{WR}$	WRITE Input. In combination with CS, this active low signal starts a new conversion.
19	BYSL	BYTE SELECT. BYSL selects high- or low-byte output during a data READ operation. (RD, CS = low). See pins 8-15.
20	$\overline{BUSY}$	Converter Status. BUSY is only low during conversion.
21	CLK	CLOCK Input. Internal clock operation, with this pin floating and unloaded, typically results in 120µs conversion time (Figure 8). This can be lowered by using an external 74HC clock source (Figure 9).
22	REFOUT	Reference Output
23	V_{SS}	Negative Supply Voltage, -5V
24	V_{DD}	Positive Supply Voltage, +15V

Note 10: High during a conversion. BUSY is a converter status flag.

Note 11: When BYSL is high, pins 9-11output a logic low. The 12-bit digital result is in DB0-DB11. DB11 is the MSB.

Calibrated 12-Bit ADC with T/H and Reference

Detailed Operation

Operating Information

Figure 5 shows an operational diagram for the MAX178. The only required passive components are a hold capacitor (CAZ) and a reference bypass capacitor and resistor. Individual pin functions are listed in the Pin Description table.

On-Chip Clock Operation

The on-chip oscillator requires no external components. Therefore, the CLK pin can be left unconnected resulting in a typical 120µs conversion time. The conversion time can be increased by adding a capacitive load on the CLK pin. The timing diagrams in Figures 6 and 7 show the resulting tracking duration for relative positions of $\overline{WR}$ and CLK. Figure 8 is a schematic for on-chip clock operation.

A new conversion is initiated by bringing $\overline{WR}$ low, with CS low. This starts a track acquisition sequence. In this state, the T/H goes into track mode. Capacitor CAZ charges to the analog input voltage minus the input offset voltage of the comparator. Note: when WR is low (with CS low), the MAX182 is in track mode. When $\overline{WR}$ goes high, tracking time is extended by another 4 to 5 clock periods (4 clock periods beginning with the first falling clock edge following the rising edge of WR). 16 to 17 clock periods are required for each conversion (Figure 7).

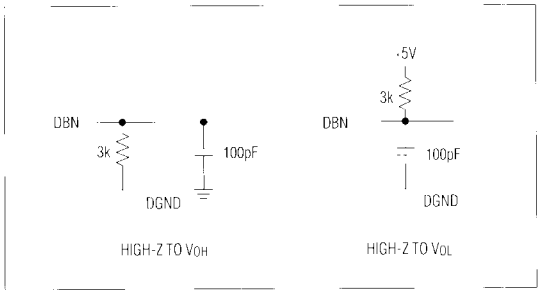

Figure 3. Load Circuits for Access Time Test (t_{11})

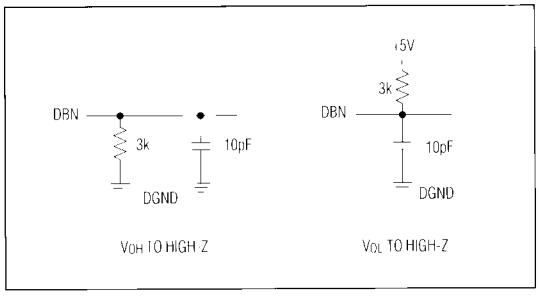

Figure 4. Load Circuits for Output Three-State Delay Test (t_{12})

The MAX178 is in track mode between conversions when $\overline{BUSY}$ is high. After the tracking sequence, the most significant bit (MSB) decision is made. Following this, the remaining 11 bits are digitized on successive clock cycles, as indicated in Figure 6. The WR pulse need not be synchronized with the internal clock.

External Clock Operation

For external clock operation, drive the CLK input with a 74HC compatible clock source (Figure 9).

The MAX178 automatically tracks for the appropriate time by means of an on-chip counter. Both WR and CS must be low to initiate a new conversion. Whenever WR and $\overline{CS}$ are low, the chip enters into track mode until WR or $\overline{CS}$ rises. After the rising edge of WR, the next falling edge of the clock starts a counter, which extends the tracking time by 4 to 5 external clock periods.

The analog input acquisition is complete at the end of the tracking period, and the signal is stored in the internal track-and-hold. The external clock source need not be synchronized with the WR pulse.

Reading Data

The 12-bit result of a conversion plus the converter status flag are accessible over an 8-bit data bus. The data is available from the MAX178 in right-justified format (the least significant bit (LSB) is the right-most bit in a 16-bit word). Two byte sized read operations are needed. The Byte Select (BYSL) input determines which byte is to be read first, 8LSBs or 4MSBs plus status flag.

It is necessary to wait for the end of a conversion to obtain valid 12-bit data from the MAX178's successive approx-

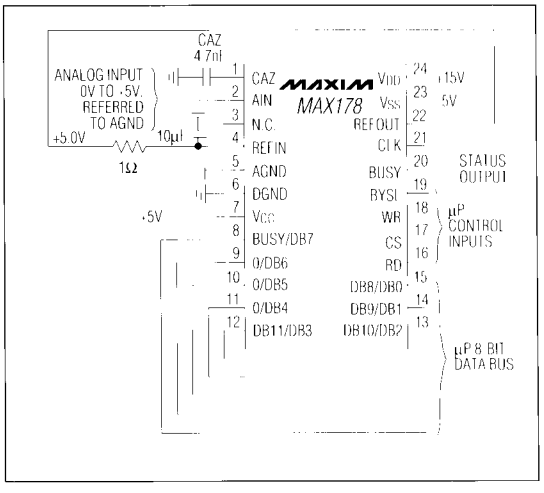

Figure 5. MAX178 Operational Diagram

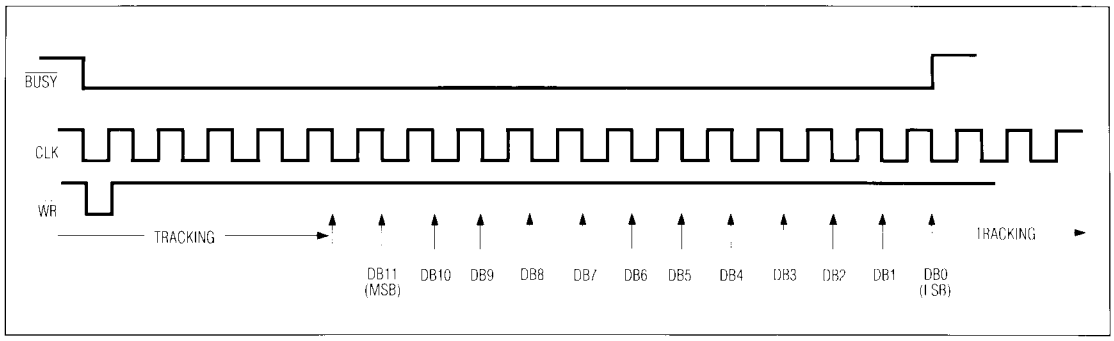

Figure 6. MAX178 Timing Diagram

imation register (SAR). If a read operation instruction is performed during a conversion, the MAX178 will dump the existing contents of the SAR onto the data bus. There are three methods to ensure correct operation:

1. Insert a software delay longer than the ADC conversion time between the conversion start and the data read operations.
2. The $\overline{BUSY}$ output is low during the conversion and high at the conversion end. Use this signal as an interrupt to the µP.
3. Poll the converter status flag, BUSY, at user-defined intervals after a conversion start. The status flag is available on DB7 during a high-byte READ. The flag is the left-most bit and can be shifted directly into the µP's carry flag for testing. BUSY is high during a conversion.

A write operation to the MAX178 during a conversion restarts the conversion.

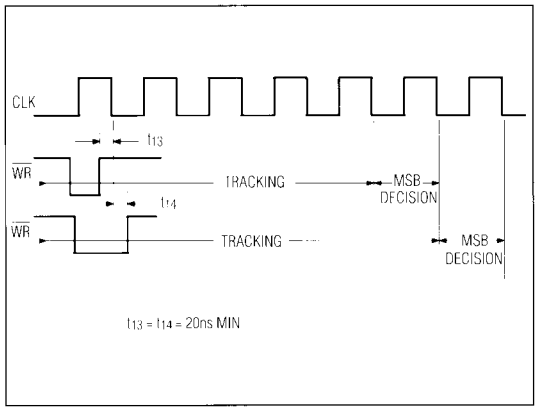

Figure 7. Width of Tracking Interval as a Function of WR Rising Edge Timing with Respect to CLK Falling Edge

Application Hints

Auto-Zero Capacitor (CAZ)

CAZ (Figure 5) must be a low-leakage, low-dielectric absorption capacitor such as polypropylene, polystyrene, or teflon. Connect the outside foil of CAZ to AGND to minimize noise. CAZ should be 4,700pF.

Clock

Figure 10 shows typical conversion time versus temperature when using the MAX178's on-chip clock. Due to variations in manufacturing, the actual operating frequency can differ from chip-to-chip by up to 20%. For this reason, it is suggested that an external clock be used when fixed conversion times are required.

Analog Inputs

The high-impedance analog input, AIN, allows simple analog interfacing. Signal sources from 0V to +5V may be connected directly to AIN without extra buffering for source impedances up to 5kΩ (Figure 11). The input/output (I/O) transfer characteristic and transition points for this input signal range are demonstrated in Figure 12 and Table 1. The MAX178 transfer characteristic has transi-

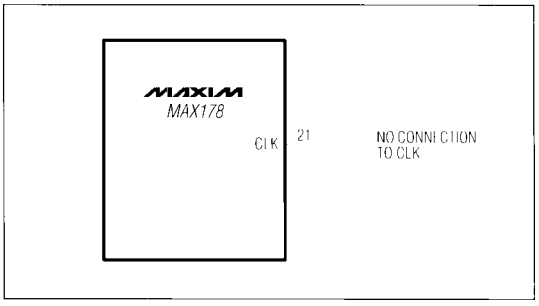

Figure 8. Internal Clock Operation

Calibrated 12-Bit ADC with T/H and Reference

tion points designed to occur on integer multiples of 1LSB. The output code is natural binary with:

1LSB = (Full Scale (FS))/4096
= (5/4096)V = 1.22mV.

For signal ranges other than 0V to +5V, use resistor divider networks to provide 0V to +5V signal ranges at the MAX178 input pins. The connection in Figure 13 shows a divider network for a 0V to +10V signal range. Resistors should be of the same type and manufacturer to ensure matched temperature coefficients. The source impedance must now be as low as possible since it adds to the resistor divider impedance.

Figure 14 shows how bipolar signals -5V to +5V are accommodated by referencing the resistor divider network to REFIN. The signal source must be capable of sinking 0.5mA with the resistor values shown. Refer to Figure 15 and Table 2 for the I/O transfer characteristic and transition points for this signal range. Output coding is offset binary with an LSB size of:

(FS)(1/4096) = (10/4096)V = 2.44mV.

To adjust bipolar zero error, apply 1.22mV (+1/2LSB) to AIN and adjust the offset of A1 so that the ADC output switches between 1000 0000 0000 and 1000 0000 0001.

Power-Supply Decoupling

Power supplies to the MAX178 should be bypassed with either a 10µF electrolytic or tantulum capacitor in parallel with a 0.01µF disc ceramic capacitor for clean, high-frequency performance. Place all capacitors as close as possible to the MAX178 supply pins.

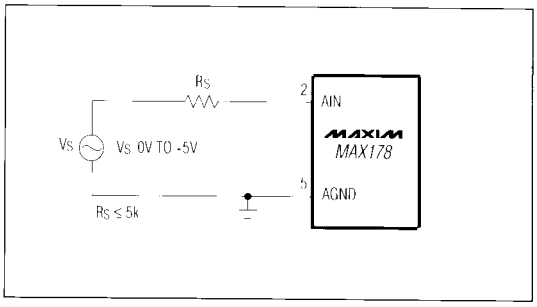

Figure 11. Unipolar 0V to +5V Operation

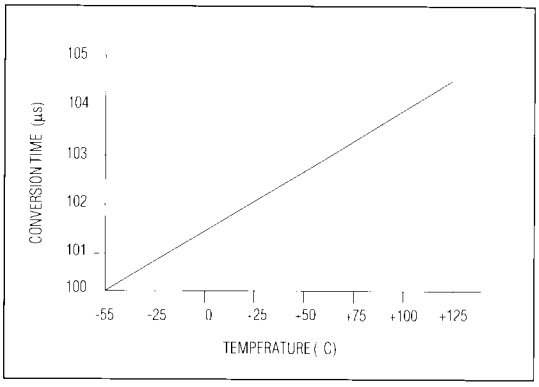

Figure 10. Typical Change in Conversion Time Variation vs. Temperature when Using Internal Clock

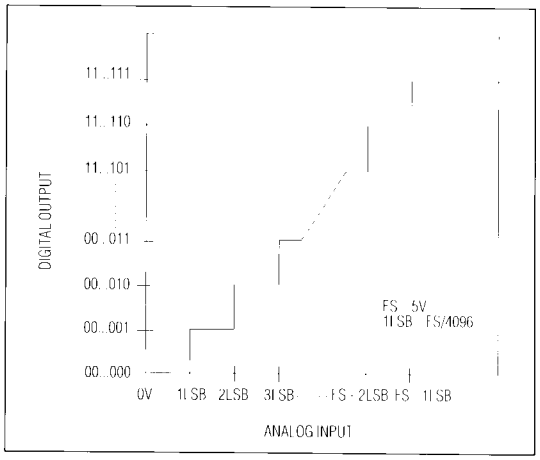

Figure 12. Ideal Input/Output Transfer Characteristic for Unipolar Circuit of Figure 11

Internal Reference

The internal reference (REFOUT) should be bypassed with a 1Ω resistor in series with a capacitor. The capacitor should be a 10µF electrolytic or tantalum in parallel with a 0.01µF disc ceramic (Figure 16). Figure 17 shows a circuit that allows input adjustment which is useful for trimming out initial (room temperature) error in the reference voltage.

Table 1. Transition Points for Unipolar 0V to +5V Operation

+4.99634	1111 1111 1111

External Reference Circuit

Figure 18 shows how to set up a MX584LH to generate a reference voltage of 5.00V. A typical adjustment range of 75mV is provided by R2. Over the commercial temperature range, the MX584LH contributes no more than ±1LSB of gain error.

During a conversion, transient currents flow at the REFIN input. To prevent dynamic errors, place either a 10µF electrolytic or tantalum smoothing capacitor in parallel with a 0.01µF disc ceramic from the REFIN pin to AGND.

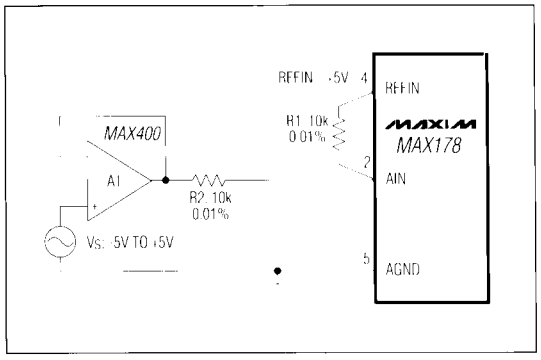

Figure 14. Bipolar -5V to +5V Operation

Calibrated 12-Bit ADC with T/H and Reference

Layout

When designing layout for a printed circuit board, keep digital and analog signal lines separated whenever possible. It is critical that no digital line runs alongside an analog signal line or near the CAZ. Guard the analog inputs, the reference input and the CAZ input with AGND.

Establish a single-point analog ground (AGND) as close to the MAX178 as possible, isolated from the logic system. Connect the single-point analog ground to the digital system ground, which is attached to DGND at one point, as close as possible to the MAX178. The following should be returned to the analog ground point: input-signal common, input guards, the CAZ, and any bypass capacitors for the reference input and the analog supplies. Low-impedance analog and digital power-supply common returns, with wide trace widths, are essential for quiet operation of the MAX178.

Noise

To minimize input noise coupling, input signal leads to AIN and signal return leads from AGND should be kept as short as possible. A shielded cable between source and ADC is suggested in applications where longer leads are required. Also, care should be taken to reduce ground circuit impedances as much as possible since any potential difference in grounds between the signal source and ADC creates an error voltage in series with the input signal.

When interfacing to continuously busy and noisy µP buses, it is possible to get errors at the LSB level. These errors exist because of feedthrough from the bus to the integrated circuit through the package. The problem can be minimized in ceramic packaged chips by grounding the metal lid. Another solution is to isolate the MAX178 from the noisy µP bus using three-state buffers.
